

Reverse Lookup

Overview:

Finding the value from a key is easy: `my_dictionary[key]`. But what if you only have the value and want to find the key?

There's no built-in function for this - you'll be writing it here.

You will practice these programming concepts we've covered in class: * Functions * Loops * Dictionaries

Deliverables

One `.py` file with code that solves the problem.

Requirements

Your task is to write a function that takes a dictionary and a value, returning the corresponding key.

For example:

```
state_capitals = {
    "Alaska" : "Juneau",
    "Colorado" : "Denver",
    "Oregon" : "Salem",
    "Texas" : "Austin"
}

print(reverse_lookup("Denver"))
# Prints Colorado
```
